Inversion Model Resistivity Curves

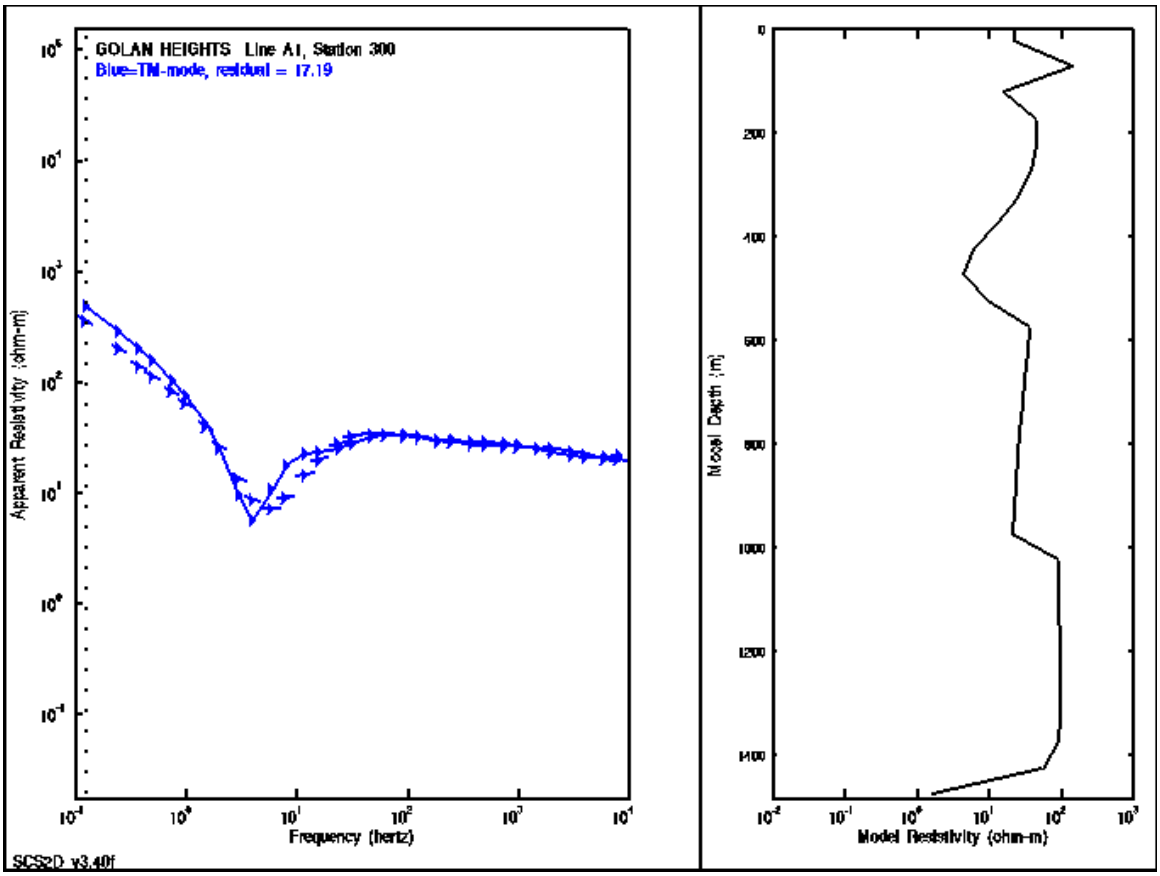

The following model plots show the results of constrained inversion models of each station from the program SCS2D. Each plot is made up of two images: the left image shows the Cagniard resistivity plotted as data points on a log-log frequency versus resistivity plot, and the resulting model as a solid line for comparison. The right image shows the model results as resistivity versus depth.

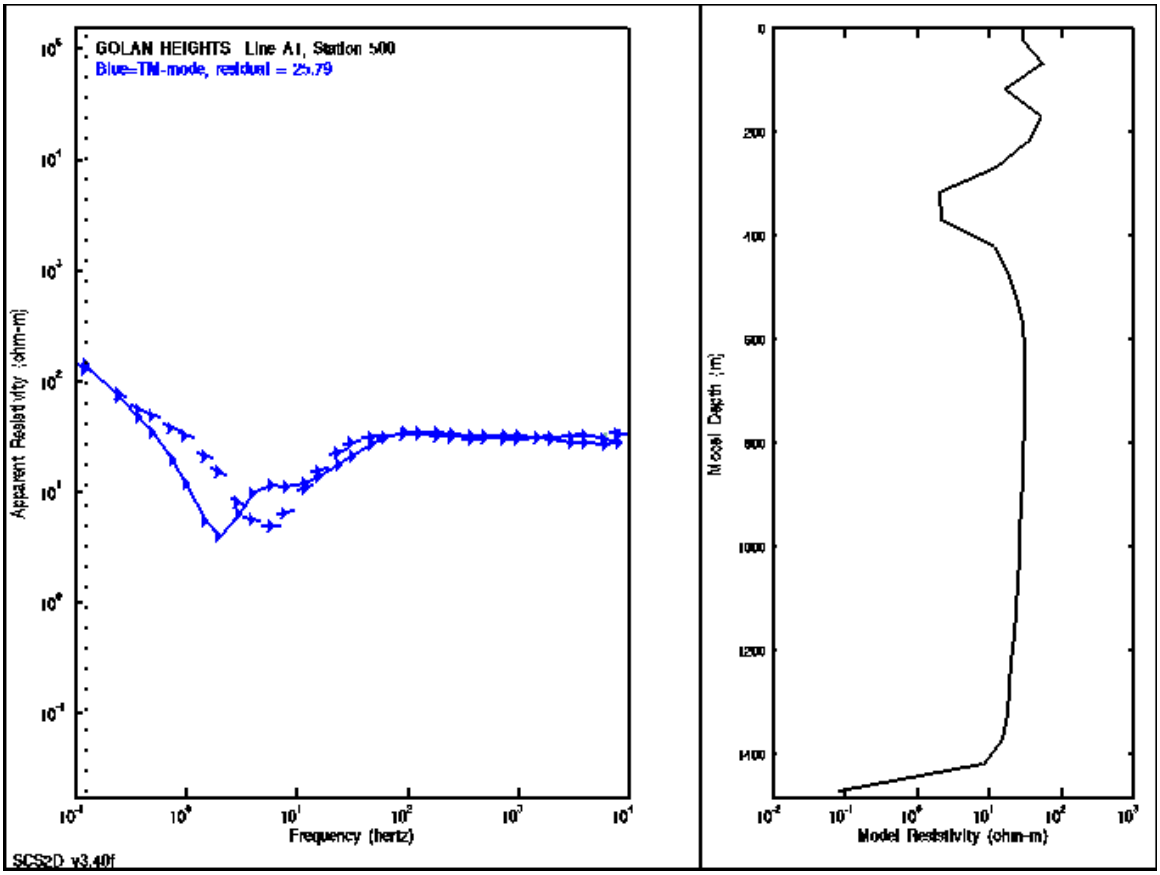

The starting model for each station is a four-layer case, based on the lithology provided by Genie in the 2013 Vinegar report. The four layers used to approximate the geology were:

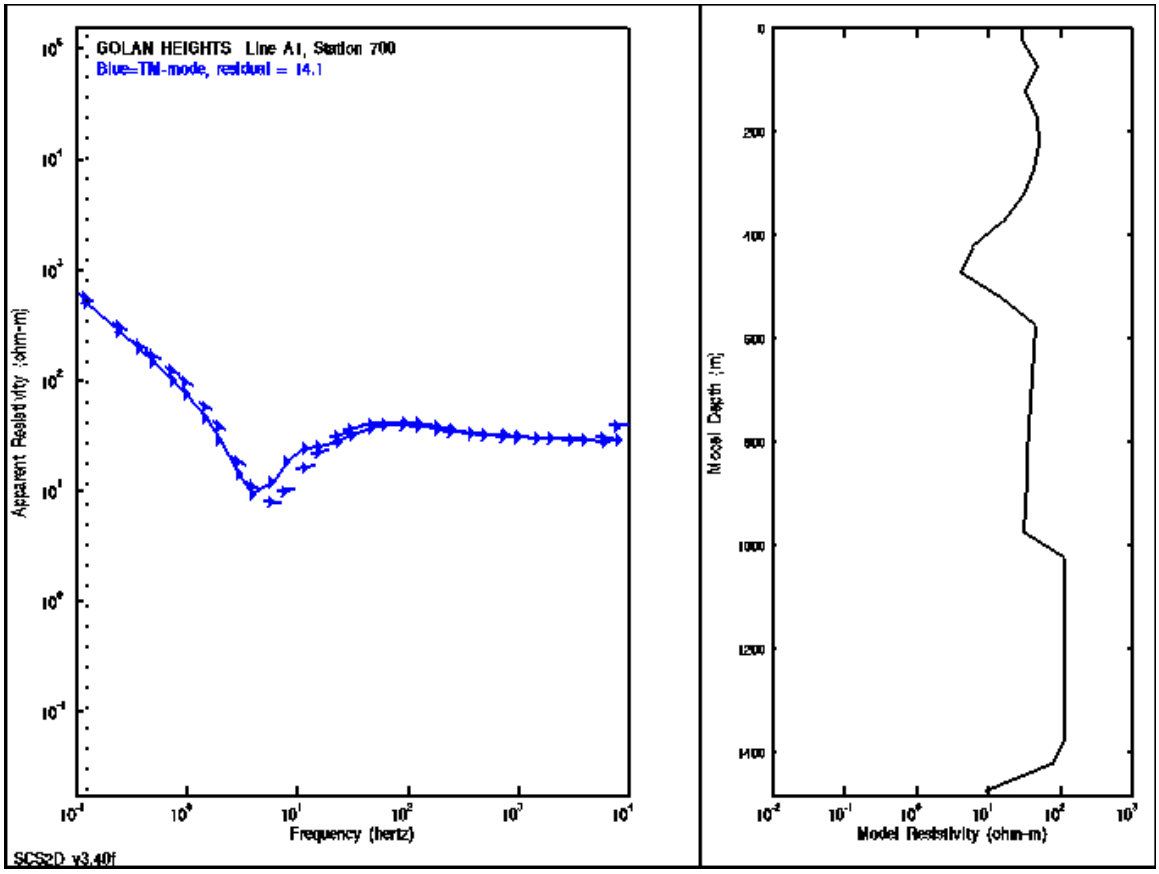

Layer 1	Basalt and cover material
Layer 2	Eocene and Taqia
Layer 3	Gareb-Upper Mishash- Mishash-Menuha formations
Layer 4	Bina

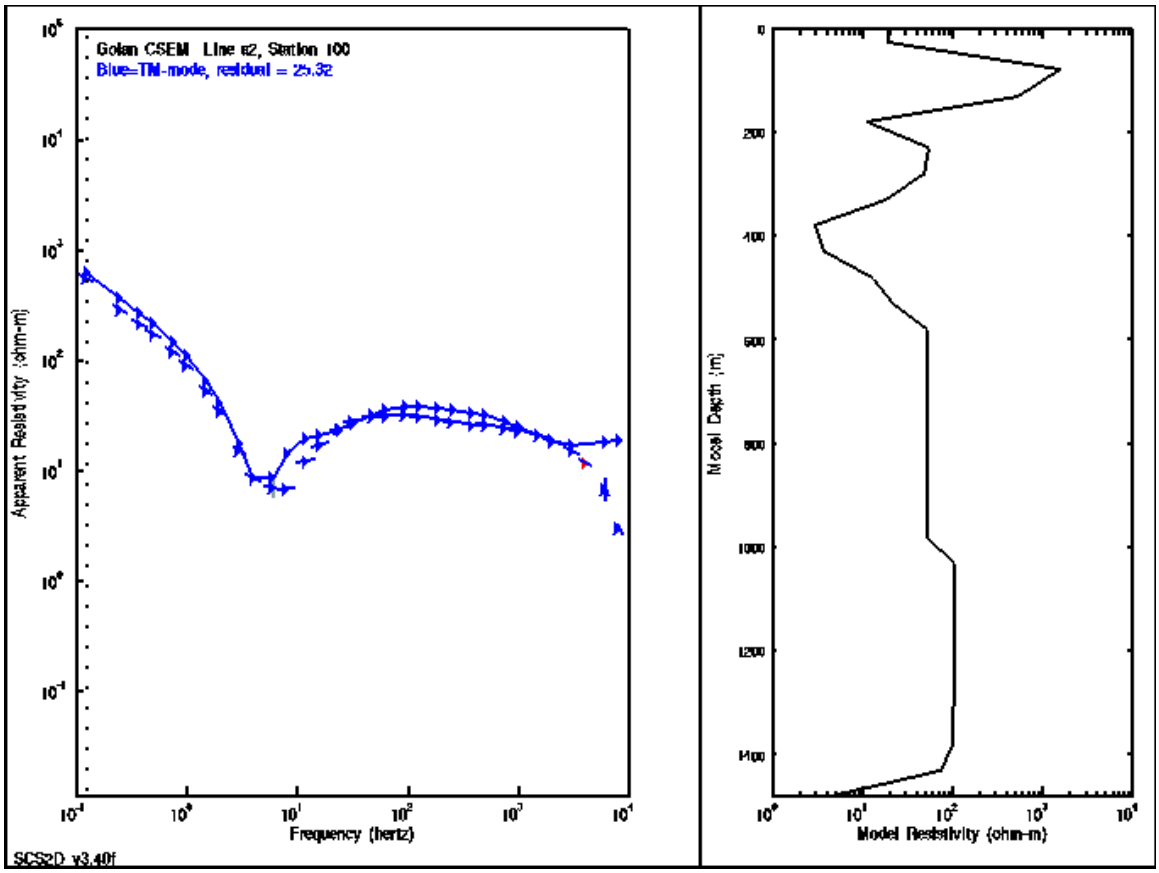

The thickness of each layer is based on the lithology of the nearest well location in the Vinegar report. In SCS2D, gradient constraints were adjusted at these layer interfaces to allow sharp, abrupt changes in resistivity at interfaces, rather than forcing smooth, gradational changes. Model fits to the data are relatively good in most cases, but very poor on a few lines (such as B-2 and E2-5), probably due to cultural noise, off-line effects from complicated geology, or a combination of these effects.
